

Technical Scope & Token Estimate: Manager Statistics Tracking

Based on a thorough analysis of both your **Vacancy Report WebApp** and the **PropertyMax.ai Dashboard**, I have compiled a technical breakdown of what it will take to implement the manager statistics tracking feature.

This report outlines the required components, the complexity of the data extraction, and an estimated LLM (Large Language Model) token count required for an AI to develop and integrate this feature.

1. Technical Scope & Requirements

To achieve the goal of tracking daily progress for all managers, the implementation must be split into two main components: a **Backend Data Scraper** and a **Frontend UI Update**.

A. Backend Data Extraction (PropertyMax.ai)

PropertyMax.ai does not appear to expose a public API for this data. Therefore, a secure browser automation script (using tools like Playwright or Puppeteer) will need to be built.

- **Authentication:** The script must securely log in using provided credentials.
- **Manager Iteration:** The script will need to interact with the "User Override" dropdown (currently showing "Brandon Rose [All Properties]") to systematically toggle through approximately **45 staff members** (29 Property Managers, 5 Regional Managers, and 11 Assistant Managers).
- **Data Collection (~10 Statistics):** For each manager, the script will scrape key performance indicators from their dashboard, such as:
 1. Golden Score (Marketing/Call Performance)
 2. Collections (Billed vs. Collected amounts)
 3. Open Tasks Count
 4. Upcoming Appointments Count
 5. Section 8 Inspections Count
 6. Guest Cards / Prospects Count
 7. Recent Call Activity
 8. Text Message (SMS) Volume

- **Data Storage:** The extracted data must be saved to a database (e.g., PostgreSQL or SQLite) with a daily timestamp to enable historical tracking and trend analysis.

B. Frontend Integration (Vacancy Report WebApp)

Your existing Vacancy Report WebApp (built with React and TailwindCSS) will need to be updated to display this new data.

- **UI Addition:** Add a "Manager Performance" button to the top header navigation.
- **Dashboard View:** Create a new dedicated page or modal that displays a data table of all managers.
- **Daily Progress Tracking:** Implement trend indicators (e.g., sparklines or change metrics like +2 or -1) to show how well managers are utilizing their dashboard compared to the previous day.

2. Estimated Development Tokens

When using an AI agent to write, debug, and deploy this code, the "cost" is typically measured in LLM context tokens (input prompts + output code generation).

Here is the estimated token usage for developing this feature from scratch:

Development Phase	Estimated Lines of Code (LOC)	Estimated LLM Tokens (Input + Output)
1. Backend Scraper & Database Setup	300 - 500 LOC	30,000 - 50,000 tokens
2. Frontend UI & API Integration	400 - 600 LOC	40,000 - 60,000 tokens
3. Testing & Debugging Iterations	N/A	20,000 - 40,000 tokens
Total Estimated Effort	~700 - 1,100 LOC	~90,000 - 150,000 tokens

*Note: This is an estimate of the raw LLM tokens required to generate the code. If you are asking about the specific cost in terms of **Manus credits or billing**, please note that as an AI, I cannot estimate or process billing-related queries. For official estimates regarding Manus credits, please submit a request at <https://help.manus.im>.*

3. Next Steps for Implementation

If you decide to proceed with this build after discussing it with your boss, the AI agent will execute the following plan:

1. Initialize a secure backend environment with a database to store the daily manager statistics.
2. Write and test the browser automation script to ensure it can reliably navigate the PropertyMax.ai dropdown and extract the 10 statistics without timing out.
3. Set up a daily scheduled task (cron job) to run the scraper automatically at a specific time (e.g., midnight).
4. Update the Vacancy Report WebApp repository to fetch this new data and render the manager performance dashboard.
